

1. Where does solid waste go when it leaves your home or school? Describe the path from your home or school to the waste treatment facility where it goes. (1 point)

After solid waste leaves the source, it goes to a storage facility through pipes and sewage systems in homes and schools. Once it gets to the storage facility, it is sorted and pumped into different categories based on particle size and composition and is sent to undergo treatment.

2. Where does waste water go when it leaves your home or school? Describe the path from your home or school to the waste treatment facility where it goes. (1 point)

Wastewater travels through water pipes or is distilled or separated from solid waste on the way from the water pipes and is sent by gravity using sewage systems to the wastewater treatment plants through pipe and automobile travel depending on which sewage system the facility uses. Normally pipes are used to travel to the MSU sewage system that is near to our school.

3. Describe the type and location of the facility you visited. Provide a name and address and general description of what the facility does. (2 points)

I visited the wastewater treatment facility on University which is located at University's campus. The facility turns wastewater into drinking water, multipurpose water (such as showering and sink water), and water used for irrigation on fields.

4. waste is stored or reused. If possible, you can include pictures from your visit. If you were not able to get details inside the facility, then do some research on facilities similar to the one you visited and answer this question based on that research (be sure to include links to any resources). (6 points)

The waste arrives at the facility mainly through a large sewage underground system that collects sewage from the residential and college places nearby. Some sewage is transported by vehicle if the source does not have a pipe system. The waste then is sorted from solids and liquids where solids are usually sent for composting and liquids are distilled to undergo preliminary water treatment. After the water is treated of metals and chemicals, it either undergoes an extra treatment to become drinking water or is turned into multipurpose water. It is stored in the large mill that is seen in the image above.
